

Concentrating axisymmetric background

Construct the prescribed blowup profile.

[Theorem 4.6](#) and [Proposition 5.5](#)

Represent the remaining residual by an annular stress

Separate a flat remainder and write the remaining momentum residual as a stress divergence, supported in a cylindrical annulus.

[Proposition 5.5](#); (5.41)

Construct two wave families

Background shear amplifies the waves; viscous dissipation makes them decay.

[Lemma 7.4](#); (7.22)

Choose the squared amplitudes

Match the averaged radial flux of tangential momentum to the leading annular stress.

[Proposition 7.5](#); (7.24)–(7.26)

Add exactly divergence-free waves

Take curls. The divergence of the leading averaged flux cancels the leading background stress divergence.

$$w = \nabla \times \mathcal{A}_{\text{wave}}$$

[Lemma 7.7](#); (9.11)
